Sponge Cup Construction A wooden cup is made by cutting an elliptical piece of wood. The cutting is done with a band saw and the cup is finished with a chisel. The cup is then sanded and given two coats of polyurethane or another finish. Sponge Cup

Use The cup is used to absorb oil by placing it on a large sponge and filling the cup with oil. The cup is then rolled over the sponge to allow oil to soak into the sponge. It is then removed and discarded. How To Operate This Machine A typical "dump" operation would be to place the kettle in the bucket and let the pump run, when the pump stops the "sink" opens allowing the melted wax or concrete to flow into the kettle, then with the "trigger" activated the kettle lifts into the bucket. Tower Truck Tankers In service for over fifty years, the Tower tanker is considered by many to be one of the greatest machines ever created.

Tower Tankers are the primary means of moving brine into and out of the production well, as well as transporting the production brine to a storage tank, gas well injection well, production facility or field brine tank. A typical configuration is a tank truck, which is an enclosed body with a low profile, mounted on a conventional tank chassis and equipped with a tank top agitator that circulates the production brine through the tank on the underside of the tank top. Brine Tech Tankers Brine Tech tankers are designed for "cold weather", meaning the brine temperature may be as low as 75 degrees F. and the bottom of the tank may be down to 40 degrees F. This is because the brine is produced in the colder seasons when the brine is located in sub-surface formations containing high levels of brine. When the tankers are used in these conditions, the tankers must operate using the brine as a "primary heat source" to keep the brine temperature inside the tanker from falling below the ambient temperature.

The tankers are not equipped with a heater. Brine Tech Tankers are equipped with three systems to ensure the brine is kept "hot" when the tanker is operating in cold weather conditions. The Brine Cooler System The brine cooler system keeps the brine temperature inside the tank by "compressing" the brine to increase the heat transfer of the brine from the 82157476af
